

**In the claims:**

1           1.       In a data communication device operable in a communication system to  
2       communicate data pursuant to a packet communication service, an improvement of apparatus  
3       for embedding control information into individual packets of the data communicated pursuant  
4       to the communication service, said apparatus comprising:  
5               a formatter adapted to receive indications representative of the data to be  
6       communicated pursuant to the packet communication service, said formatter for formatting  
7       the indications into the individual packets, each of at least selected ones of the individual  
8       packets formatted to include a control field that is populated with values that identify session  
9       control information, used in control of effectuation of the packet communication service.

1           2.       The apparatus of claim 1 wherein the individual packets into which the control  
2       information is embedded comprise RTP-formatted packets, and wherein said formatter  
3       formats RTP-formatted packets to include the control field.

1           3.       The apparatus of claim 2 wherein each of the selected ones of the RTP-  
2       formatted packets comprise a header part and a header extension part and wherein the control  
3       field is embodied at the header extension part.

1           4.       The apparatus of claim 3 wherein each of the header parts of the RTP-  
2       formatted packets includes an indication field to indicate presence of the header extension part  
3       and wherein said formatter further populates the indication field to indicate the presence of  
4       the header extension part.

1           5.       The apparatus of claim 3 wherein the header extension part comprises a first  
2       portion and at least a second portion, the first portion comprising the control field and wherein  
3       said formatter populates the first portion of the header extension part with values of the  
4       control information.

1           6.       The apparatus of claim 3 wherein the control field is selectably populated with  
2       first values, the first values indicating remaining portions of the header extension part to be  
3       non-packet-communication-service, control-information related.

1           7.       The apparatus of claim 3 wherein the control field is selectably populated with  
2       second values, the second values indicative of delay of communication of subsequent data  
3       packets communicated pursuant to the packet communication service.

1           8.       The apparatus of claim 3 wherein the control field is selectably populated with  
2       third values, the third values indicative of termination of communication of subsequent data  
3       packets pursuant to the packet communication service.

1           9.       The apparatus of claim 3 wherein the control field is selectably populated with  
2       fourth values, the fourth values indicating the data of the data packet associated therewith to  
3       be application-dependent.

1  
2           10.      The apparatus of claim 3 wherein the control field embodied at the header  
3       extension part includes a first section of a three-bit length.

1           11.    The apparatus of claim 10 wherein the control field embodied at the header  
2 extension part further includes a second section of a seventeen-bit length.  
3

          12.    The apparatus of claim 11 wherein the first section comprises an INFO field  
and wherein the section comprises a defined-by-profile field.

1  
2           13.    The apparatus of claim 11 wherein the first section and the second section are  
3 separated by at least a first bit forming a padding field.

1           14.    The apparatus of claim 11 wherein the control field embodied at the header  
2 extension part further includes a third section, the third section populated with values when  
3 the first section is of selected values.

1           15.    The apparatus of claim 1 wherein the packet communication service comprises  
2 a real time communication service and wherein the control field that said formatter formats  
3 each of the at least selected ones of the individual packets to include comprises pause  
4 information associated with subsequently-transmitted ones of the individual packets.

1           16.    In a method of communicating in a data communication system having a data  
2 communication device for communicating data pursuant to a packet communication service,  
3 an improvement of a method for embedding control information into individual packets of the  
4 data pursuant to the packet communication service, said method comprising:

5 obtaining indications representative of the data to be communicated pursuant  
6 to the packet communication service; and

7 formatting the indications into the individual packets, each of at least selected  
8 ones of the individual packets formatted to include a control field that is populated with  
9 values that identify session control information used in control of the packet communication  
10 service.

1 17. The method of claim 16 wherein the individual packets into which the control  
2 information is formatted during said operation of formatting to include comprise RTP (Real  
3 Time Protocol) packets.

1 18. The method of claim 17 wherein each of the selected ones of the RTP-  
2 formatted packets comprise a header part and a header extension part and wherein the control  
3 information formatted during said operation of formatting is formatted into the header  
4 extension part.

1 19. The method of claim 16 wherein the packet communication service comprises  
2 a real time communication service and wherein the control field into which each of the at least  
3 the selected ones of the individual packets is formatted to include comprises pause  
4 information associated with subsequently transmitted ones of the individual packets.

1 20. The method of claim 16 further comprising the operations of:  
2 sending the individual packets to a data receiving device;

- 3                    detecting, at the data receiving device, the individual packets; and
- 4                    extracting the control information therefrom.
